A New Species of Tricrothyodes with Notes
(Ephemeroptera: Tricrothyidae)

RICHARD E. ALLEN
California State University, Los Angeles

ABSTRACT
Descriptions and figures are presented for Tricrothyodes carvenii Allen, n. sp., and the nymphs of the North and Central American Tricrothyodes are placed in two species groups, the abalineata-group and the carveni-group.

A collection of nymphal mayflies on loan from the Academy of Natural Sciences of Philadelphia includes an undescribed species of Tricrothyodes, T. carveari n. sp., which is closely related to T. compadrensis Klimpel & Allen, T. dimorphismus Allen, and T. edemendi Allen. The nymphs of Tricrothyodes typically possess triangular-shaped specular gills that are angularly set off (Fig. 1), whereas the above-mentioned species have subterminal specular gills that are rounded medially (Figs. 2-5).

The shape of the specular gills is of taxonomic importance and two groups of related species are recognized for the nymphs of the North and Central American Tricrothyodes, the abalineata-group and the carveni-group. T. abalineata Benay~ T. minuta Traver (~ 'Julie Traver'), T. minuta Allen & Brune, T. carveni Allen & Brune. T. carveni-group includes T. compadrensis, T. curvata, T. dimorphismus, and T. edemendi. The nymphs of T. allista (Neeslen), T. abalineata McDannough, T. apiculata (Katon), T. bicula Traver, T. bertacii Traver, T. stingina McDannough, and T. vocans Traver are undescribed and assignable to species-group at this time.

abalineata-group
Characters that would serve to distinguish the nymphs of the five species now included is the abalineata-group have not been established at this time. Nymph assignable to this species-group are distributed from Central America to northern British Columbia (43°42' N. latitude) in western North America and Newfoundland (47°34' N. latitude) in eastern North America.

carveni-group
The five species included in this species-group have a restricted latitudinal range and are known only from northern Mexico (ca. 23°45').

The research upon which this report is based was supported by National Science Foundation Grant GMS 75-7766. Received for publication January 14, 1976.
N. latitude) to northern Utah in the western United States (ca. 40°45' N. latitude) and to northern Arkansas in the central United States (ca. 35°10' N. latitude).

The following key will serve to distinguish the nymphs of the *carusius*-group.

### KEY TO THE SPECIES

1. **Maxillary palp 1-segmented; femora with some irregularly spaced long and short marginal setae (Fig. 7ab)**
   - 2

2. **Maxillary palp absent; femora with numerous regularly spaced long marginal setae (Fig. 6a,b)**
   - 3

2(1). **Tarsal claws with marginal denticles and single subapical denticle near apex; operculate gills with black apical macula (Fig. 2); sexes dimorphic, males with large compound eyes**
   - *doritus*

3. **Tarsal claws with marginal denticles, without subapical denticle near apex; operculate gills suffused with black (Fig. 3); sexes not dimorphic, males with small compound eyes**
   - *carusius*

3(1). **Tarsal claws with marginal denticles and paired subapical denticles (Fig. 6c); operculate gills suffused with black (Fig. 5); body 5.0-6.0 mm in length**
   - *corpalentus*

4. **Tarsal claws with marginal denticles, without paired subapical denticles (Fig. 8); operculate gills with apical U-shaped macula (Fig. 4); body 3.0-4.0 mm in length**
   - *edmundtii*

### Tricorythodes carusius n. sp.

**Nymph.** Length: body 5.0-6.0 mm; caudal filaments 4.0-5.0 mm. General color brown with dark markings. Head dark with pale markings; large pale macula below median ocellus, pale around compound eye; maxillary palp 1-segmented, without apical seta. Thoracic nota pale with irregular black markings; thoracic nota with moderately long setae; legs yellow with proximal tibial macula; femora marginal setae long and short, sparse, and irregularly spaced as in Fig. 7ab; twice as long as broad; hind femora 40% longer than fore femur; tarsal claws with 6-8 small marginal denticles, without sub-marginal denticles. Abdominal terga yellow with wide dark transverse band; terga with...
long setae; posterolateral projections poorly developed on segments 7-9; operculate gill subovate, rounded medially (Fig. 3), suffused with black; abdominal sterna pale. Caudal filaments pale.

**Types.** Holotype: mature nympha, White River, ca. 2.8 mi. ENE Salada, Independence Co., Arkansas, 30-31-VII-74, J. V. Richardson, in collection Academy of Natural Sciences of Philadelphia. Paratypes: 2 nymphs, same data as holotype, one each in collection Academy of Natural Sciences of Philadelphia and California State University, Los Angeles.

*Tricorythodes carpalinus* Kilgore & Allen

This species was described from a single nympha collected in Caiin Co., New Mexico.

**Nymph.** Length: body 4.5-5.5 mm; caudal filaments 5.0-6.0 mm. General color pale with dark brown and black markings. Head pale to light brown; occipus with dark brown markings; head with long setae; maxillary palpi absent. Thoracic nota yellow with dark brown markings; thoracic nota with moderately long aseae; legs yellow with diffuse black markings; fore femora with 2 small maculae, femoral marginal setae long, numerous, and regularly spaced (Fig. 5a,b); fore femora as long as broad; hind femora 35% longer than fore femora; tarsal claws with 6-8 basal marginal denticles and 7 submarginal denticles near apex (Fig. 6c). Abdominal terga yellow with broad dark brown transverse band; terga with long setae; posterolateral projections poorly developed on segments 7-9; operculate gills rounded medially, with diffuse black markings (Fig. 5). Caudal filaments pale.

*Tricorythodes dimorphus* Allen

This species was described from a small series of nymphs collected in Arizona and New Mexico, and in 1963, Kilgore & Allen reared and described the male imago from southern California.

**Male Nymph.** Length: body 2.5-4.5 mm; caudal filaments 2.0-3.5 mm. General color yellow to light brown with black markings. Head yellow to light brown; compound eyes large; maxillary palpi 1-segmented, with apical setae. Thoracic nota yellow to light brown with regular black markings; legs yellow with black markings; femora with variable black markings; tibiae and tarsi with apical black maculae; femoral marginal setae long and short, sparse, and irregularly spaced (Fig. 7a,b); fore femora twice as long as broad; hind femora 35% longer than fore femora; tarsal claws with 6-8 marginal denticles, and single submarginal denticle near apex. Abdominal terga black

with variable yellow to light brown markings; legs with long setae; postero-dorsal projections poorly developed on segments 7-9; apicalate gills rounded mesally, with black apical marking (Fig. 2). Caudal filaments yellow.

**Female Nymph.** Length: body 4.0-6.5 mm; caudal filaments 3.0-4.0. General color brown. Compound eyes small. Other characters as in male except for usual sexual differences.

*Tricoryphodes edmundi* Allen

The nymphs of this species were described from a small series collected in Utah and northern Mexico.

**Nympha.** Length: body 3.0-4.0 mm; caudal filaments 1.0-2.0 mm. General color brown with black markings. Head brown; head with long setae; labial palp absent. Thoracic nota brown with variable markings; nota margined with long setae; lep yellow; middle and hind femora with variable markings; tibiae and tarsi with apical black maculae; femoral marginal seta long, numerous, and regularly spaced as in figure 64a,b; fore femora less than twice as long as broad; hind femora 40% longer than fore femora; caudal claws with 5-7 marginal denticles (Fig. 8). Abdominal terga brown to yellow with dark transverse bands; postero-dorsal projections poorly developed on segments 7-9; apicalate gills rounded mesally, with black U-shaped marking (Fig. 4). Caudal filaments pale.
