ABSTRACT

The mayfly fauna of California consists of 155 species in 44 genera among 15 families. Previous data and new data (from 23 major collections) are given for all species and include first published state data for 53 of the species. In addition, 1,720 new county records involving all 58 California counties are given for 140 of the species. Less than 10 percent of the species appear endemic to California

INTRODUCTION

Eaton (1884, 1885) in his landmark monograph of world mayflies (Eaton 1883-88) was the first to report any mayflies from what is now the state of California. These included six species now known to be *Ameletus dissitus* Eaton, *Baetisca lacustris* McDunnough, *Rhithrogena hageni* Eaton, *Paraleptophlebia memorialis* (Eaton), *P. rufivenosa* (Eaton), and *Siphonurus occidentalis* (Eaton), with *P. memorialis* technically the first species reported from the state. The main contributors of first published state records of species in California during the 20th Century included Traver (1934, 1935a,b) with 27 first records, Day (1951, 1952, 1954a,b, 1955, 1956) with 19 first records, and Mayo (1939, 1951, 1952a,b) with 10 first records. Twenty-eight additional authors have contributed first published records for California, and 41 now valid species were originally described from California, bringing the total of published records of valid species previous to the present work to 102. Day (1956) offered the only historical faunal treatment of California mayflies, which included 85 now valid species.

The present work represents part three in our series on the mayflies of the far western conterminous USA, following our treatments of Washington state (Meyer and McCafferty 2007a) and Oregon (Meyer and McCafferty 2007b). Alaska was treated extensively by Randolph and McCafferty (2005). Our study of California has added 53 species to the previously published 102, bringing the current total number of valid mayfly species known from the state to 155. This includes the confirmation with extensive new data of four species that had been reported previously only in unpublished theses (see data below). Mayflies were found in all 58 California counties (Fig. 1) based on source data from 23 institutional and private collections. We provide 1,720 new county records for 140 species of the 155 species included in our account. Based on recent revisionary works and recent records of mayflies from other areas, there remain only 14 species of mayflies that are possibly endemic to California: *Ameletus imbellis* Day, *Baetis diablus*

Fig. 1. California counties.

Day, *B. palisadi* Mayo, *Choroterpes terratoma* Seemann, *Edmundsius agilis* Day, *Epeorus lagunitas* (Traver), *Paraleptophlebia altana* Kilgore and Allen, *P. associata* (McDunnough), *P. cachea* Day, *P. californica* Traver, *P. clara* (McDunnough), *P. helena* Day, *P. quisquilia* Day, and *P. zayante* Day.

All California species were verified via identification. The style of presentation is after Meyer and McCafferty (2007a, b). New data are based on larval samples unless "A" for alates, or "A,L" for both alates and larvae, are appended to the collection data. Only surnames of collectors are given when known. Records or listings unaccompanied by collection data are not recognized as previous data (see McCafferty 2000).

Material on which new records are based are housed at the following institutions or private collections, and are indicated by upper case acronyms as follows: Bureau of Land Management/Utah State University National Aquatic Monitoring Center BugLab, Logan, UT (BLAB); Monte L. Remarks.—Identifications of larvae as *F. quilleri* from northern California as recorded above must be rechecked in the future, because as pointed out by McCafferty et al. (2008), it is quite possible that many will prove to be the larvae of *F. thermophilos* (McDunnough), which became known (McCafferty et al. 2008) after the above identifications were made. WPM rechecked what limited material of this was available at PERC, and found that out of five vials of northern California larvae, one was indeed *F. thermophilos* (from Humboldt County, see below). In a similar respect, larvae from southern California identified as *F. quilleri* need to be rechecked to see if any are actually *F. sonora*, recently discovered in southern California (McCafferty et al. 2008); see also remarks under *F. sonora*, below.

Fallceon sonora (Allen and Murvosh)

Previous data.—McCafferty et al. (2008): SAN BERNARDINO (Mojave R).

Remarks.—As pointed out by McCafferty et al. (2008), this species, presently known only from larvae, may prove to be a junior synonym of *F. eatoni* (an older name associated only with adults at this time). The latter species is herein shown for the first time to occur in California.
