

NOTE

Reinstatement of *Serratella serratoides* (McDunnough) and Status of *Ephemerella molita* (McDunnough) (Ephemeroptera: Ephemerellidae)

Recent global study of Ephemerellinae (Ephemeroptera: Ephemerellidae) (sensu McCafferty and Wang 2000) has revealed that the status and synonymies of two nominal species should be adjusted. *Ephemerella molita* McDunnough is designated here to be a *nomen dubium*, and *Serratella serratoides* (McDunnough) is removed from synonymy with *E. molita*. Jacobus and McCafferty (2002) considered the two species to be equivalent, based on their observation that the female adult holotype of *E. molita* has sternal markings similar to those of *S. serratoides* and that the coloration of its caudal filaments fall within the range of color variation of *S. serratoides*. We now recognize that the holotype of *E. molita* is also indistinguishable from variants of several other Ephemerellinae species that were not examined as part of the Jacobus and McCafferty (2002) study. These species each have rows of dark maculae on their abdominal sterna and include, for example, the Nearctic species *E. needhami* McDunnough (e.g., McDunnough 1931, Traver 1935, Burks 1953, Allen and Edmunds 1965) and the widespread Palearctic, and possibly Holarctic, species *E. notata* Eaton (e.g., Eaton 1887, Schoenemund 1930: fig. 101, Ulmer 1932: fig. 44, Landa 1969, Elliot and Humpesch 1983: fig. 33, Studemann et al. 1992: fig. 341, Ishiwata 2001). Although the presence of sternal maculations on these *Ephemerella* Walsh species has been documented extensively, no comparisons to them were made by Jacobus and McCafferty (2002), because at that time *E. molita* was thought to be part of the *Ephemerella serrata* Morgan

species group (McDunnough 1931, Traver 1935, Allen and Edmunds 1963), which is recognized widely now as the genus *Serratella* Edmunds (Edmunds 1959, Tshernova 1972, Allen 1980). The confusion surrounding *E. molita* is due in part to the historical lack of global comparisons of Ephemerellinae species and to difficulties surrounding proper identification of female adult Ephemerellinae. Many female adults are indistinguishable from one another using traditional external morphological characteristics. Examination of eggs could contribute to the resolution of the identity of *E. molita* (Jacobus and McCafferty, unpublished), but such action would require destruction of the holotype, the only *bona fide* specimen associated with the name *E. molita* (McDunnough 1930). McDunnough (1931) mistakenly reported a paratype from New Brunswick (Jacobus and McCafferty 2002), and Traver's (1932) discussion appears to be an inadvertent error because no male adult has been associated with the species. *Ephemerella molita* should not be confused with *E. mollitia* Seemann, a species name that is synonymous with *Ephemerella dorothea infrequens* McDunnough (Jacobus and McCafferty 2003).

Unfortunately, *E. molita* has been reported several times since Jacobus and McCafferty (2002) modified its concept. In most of these instances (e.g., Kluge 2004, DeWalt and Heinold 2005, Chandler et al. 2006, DeWalt et al. 2007, Parker et al. in press), specimens are representatives of *S. serratoides*. McCafferty et al. (2006) discussed a report of *E. molita* from Iowa that was

based instead on a misidentification of *E. needhami* (McCafferty et al. 2003). An Arkansas record of *S. sordida* (McDunnough) (Peters and Warren 1966) that Jacobus and McCafferty (2003) treated as a misidentification of *E. molita* is referable to *S. serratoides*.
